Integrated Resource Planning Training for Decision Makers

Day 1, Session 2 Generation and transmission planning - the heart of an IRP

8 March 2021
Content and objective

Content:
- Why is it important to develop an Integrated Resource Plan (IRP)?
- What information is available in an IRP that can help decision making?
- Main elements of an IRP
- What is wrong with Levelised Costs of Energy (LCOE) and why more sophisticated modelling is needed for least-cost planning?

Objective:
- The objective of this session is to understand:
  - What is an IRP and its main elements
  - Why an IRP may be a useful tool
  - What information an IRP can provide
Electricity’s unique properties as a commodity

- There are high fixed-costs to build the necessary infrastructure to transmit and distribute the electricity to end-users.
  - It requires planning looking at the sector in the long run
  - Asset lives more than 20 years

- It cannot be stored as electricity
  - It must be created to be used immediately and the demands varies over short intervals
  - Fly wheels, batteries, pumped storage all convert electricity into other forms of energy and then convert the energy back to electricity

- There is a cost to storage
  - Once electricity is produced, it is impossible to tell which generator produced which electrons once it is pooled in the network.

An investment decision taken today will involve high fixed costs and will have an impact in the long run due to long asset lives

Need to assess investment decisions looking the impact in the short, medium and long run
Why is it important to develop an Integrated Resource Plan (IRP)?

**Why an IRP is needed:**

- Planning by vertically integrated utilities
- Single-buyers deciding what sort of capacity to contract and at what price
- TSOs identifying the best generation locations for network planning
- Interconnection planning with neighbouring countries
- Estimates of supply costs going forward, which informs policymaking and tariff setting
- Assuring International Financing Institutions (IFIs) of the robustness of their investments

---

### Integrated Resource Plan (IRP)

An IRP is a very useful tool for planning by utilities

- An IRP can provide information for the following planning related questions:
  - In which technologies should I invest?
  - When do I need to invest?
  - How much it will cost me?
  - What is the impact from retiring power plants?
  - How can I ensure security of supply?
  - Can I cover my energy and peak demand?
  - Can I reduce my operating costs?
  - Can I plan under uncertainly?
  - Can I achieve my renewable energy targets?
  - What should I do if demand rapidly increases?
  - And many others

- Can you think of a decision you had to make recently at your business? Let’s see if an IRP could inform your decision.

- Example of information given by an IRP regarding the schedule of investments for a system in West Africa:
  - All types of available options of power plants were assessed to derive a solution that minimises costs and covers peak demand, energy demand and ancillary service requirements.
  - When an investment is needed, how much it will cost, which technology I should select and which Solar PV sites should be prioritized.

- You could also investigate how much would it cost to the Utility to force the development/retirement off a generation asset in the energy mix.

An IRP can also be used to inform policy decisions

- Policy makers would want to know the implications of policy decisions
  - An IRP can provide useful insights on the implication of policy decisions
- For example an IRP can provide useful information for setting renewable energy targets:
  - What is the cost of achieving a renewable energy target?
  - Or
  - What is the implication on costs if I set x% as a renewable energy target.
  - Can we achieve the target with the available candidate power plants/resources?

Example from an IRP on the impact on costs from different policy targets to inform policy makers:
- **Renewable energy target** - how much would it cost me to set a renewable energy target to 30% by 2030?
- **Security of supply target** - How much would it will cost to set a 50% domestic energy restriction? Can it be achieved?

Overview of an IRP

Integrated Resource Plan (IRP)

Resources
- Coal, gas
- Wind, Solar
- Hydro
- Geothermal
- etc.

Demand
- Peak (MW)
- Energy (MWh)
- Demand profile
- Demand Side Measures (DSM)

Generators
- Technical, economic and financial characteristics of power plants

Networks
- Grid stability
- Extensions
- Upgrades
- Interconnections

Planning criteria

System modelling (Scenarios / simulations)

- Dispatch
- Volumes
- Costs

Least cost generation, transmission and supply development plan

Key insights an IRP can provide:

- Generation and transmission plan under different market conditions including capital, fixed and variable operating costs
- What capacity to contract and at what price for PPAs
- Which are the best generation locations and where should the grid be reinforced
- What could be the supply costs going forward
- What could be the tariff going forward
- Prove that an investment is necessary and legitimate to secure financing
An IRP initially assesses the available resource for power generation

- **Coal** – domestic or imported, type (lignite, anthracite, etc), heat value, transportation costs, price, etc.
- **Natural Gas** – domestic or imported, gas infrastructure costs (LNG, pipelines, etc), heat value, transportation costs, etc.
- **Crude Oil distillates (Diesel, HFO, LFO, etc)** – domestic or imported, heat value, transportation costs, price, etc.
- **Wind, Solar, Geothermal, Biomass** – available resources, locations, volumes, associated costs, etc.
- **Hydro** – available resources, locations, volumes, associated costs, etc.

Example for the assessment of Solar PV candidate projects in an IRP

- Identification of possible Solar PV sites for development
- Shortlist of potential sites to be developed after the application of exclusion criteria (Characterisation of land, exclusion areas, costs by site, grid availability, etc.)
- The shortlist of candidate Solar PV sites is assessed in the IRP to conclude on the least cost options to be developed.
An IRP includes an assessment of electricity demand

- The main elements of the electricity demand for power system planning in an IRP cover:
  - **Energy (GWh)** demand forecast – sets the total amount of energy that needs to be supplied.
  - **Peak (MW)** demand forecast – sets the total amount of capacity that needs to be developed for generation, transmission and distribution.
  - **Load shape** – sets the amount of capacity/energy that has to be satisfied at any given hour. It will determine how much a power plant will operate within a day/year.
  - **Demand side measures** – how the demand may be influenced by demand side measures such as energy efficiency, roof top solar PV, etc.

- The demand is not the same at all times and requires different amounts of generation in each interval.
- While generators do not constantly operate to full capacity, capacity must be sufficient to meet peak demand.
- The network has to be designed to be able to cover the peak demand.
## Typical requirements of electricity demand forecasts

<table>
<thead>
<tr>

</tbody>
</table>
An IRP includes an assessment of the generation least cost plan

- The objective of the generation least cost plan is to establish the
  - long term generation plan
  - that meets the forecast electricity demand
  - at the lowest **economic** cost
  - given policy and reliability targets.

- The plan establishes the mix of
  - import contracts and new generation capacity
  - that results in the lowest cost in present value, real terms.

</tbody>
</table>
Levelised Costs of Energy (LCOE) compare power plants costs. Why more sophisticated modelling is needed for power planning?

- **LCOE** provide a simple, common basis for comparing generating technologies
  - But technologies are not the same
  - One kWh of electricity is not necessarily as valuable as another:
    - A kWh at peak worth more than at night
    - A dispatchable kWh worth more than non-dispatchable
    - A power plant can also provide other services
  - Does not tell you when to invest
  - Does not capture technical constraints
  - Dynamic dispatch decisions are necessary to assess hydro, pumped storage and batteries
  - Does not capture the intermittent nature of RES and grid constraints

- **LCOE example for a Southern African country (2018)**
  - It does not tell you when, for how long and if will be dispatch, operational constraints (e.g. minimum stable load or ramping restrictions for thermal plants), if peak can be met, etc.

Source: Economic Consulting Associates (ECA) analysis, 2018
Analysing renewable energy (RES) generation in an IRP

- **RES generation is intermittent**
  - Sometimes Solar PV produces electricity and sometime not
  - Hydro generation is constrained by the amount of water that is available
  - Wind generation is generally characterised by volatility
    - For long-term planning, it is uncertain whether it will be windy on a Wednesday evening peak in June for example.
  - Energy is produced when resources are available

- **RES generation has essentially zero variable costs**
  - When energy is available it is dispatched first

- **RES generation may not match the system load profile**
  - Solar PV may not be able to contribute to capacity requirements in systems with an evening peak

- **Fast response reserves may be necessary**

- **Renewable energy has to be assessed in combination with other technologies and at a granularity that can capture its intermittent nature**

---

**Solar PV in Jamaica does not provide peak capacity**

- **California’s changing load curve from 2012 to 2020**
  - Increased solar penetration contributes to ‘duck curve’ effect on daily load curve
  - Need for fast ramp up capacity to meet evening peak as solar declines

Source: Economic Consulting Associates (ECA) analysis, 2018

Source: California ISO, What the duck curve tells us about managing a green grid, 2013
The objectives of transmission development plans are to:

- Prepare a least-cost economic transmission development plan
- Ensure the grid can meet demand
- Ensure the grid can operate reliably
- Integrate new power generation facilities
- Enable power exchange (e.g., imports or exports)

The transmission plan builds on the demand forecast and the generation expansion plan.
Reliability criteria in an IRP set system reliability levels that have to be respected by generation and transmission

- **Generation planning criteria**
  - *Reserves margin* – how much more capacity is needed to support the reliable operation of the system
  - *Accepted LOLP/EENS* – what is the accepted level of the system not being able to meet the demand

- **Networks planning criteria**
  - *‘N-1’ reliability level* – the system shall be able to meet peak demand even with one transmission line, main power transformer or unit for reactive power compensation out of service.
  - *Voltage levels* – Minimum and maximum voltage levels during normal and contingency operation.
  - *Capacity* – Maximum thermal loading of equipment.

### Indicative planning criteria for SAPP member countries

Scenarios and sensitivities in an IRP help to plan under uncertainty

- Scenarios can be used to model uncertainty, policy targets and market conditions in an IRP
  - It can show the least cost plan under different market outcomes
    - Demand, pricing, timing, costs, available options, costs of externalities, etc.
  - It can show the impact from different policy decisions
    - Renewable energy targets, security of supply, national targets
- Sensitivities can be used to identify the robustness of the results
  - Demand forecast, fuel costs, investment costs, national targets, emission costs, discount rates, etc.

The results of an IRP are highly sensitive to input data

- Thus there is a need consensus on key assumptions; and
- The relevant agencies (key stakeholders) need to work together in deriving criteria and assumptions
- You need to establish databases to effectively and efficiently develop IRPs

Key inputs of an IRP:
- The forecast electricity demand (MW and GWh)
  - The forecast load shape (i.e. the MW demand in each hour of the year)
- The available power and energy of hydro electric plants
- The security standards
  - Reserves margin or accepted LOLP/EENS
- The costs of existing, committed and candidate generating plants
- Cost of imports
- The projections of fuel prices
- Scenarios
- The discount rate
Main outputs of an IRP

- The Net Present Value of costs associated with each scenario
  - A measure to compare costs among scenarios, different market conditions and policy decisions
- A forecast of the operating costs of the business
- An approximate operating schedule of power plants and associated costs
- Investment schedule and investment requirements
- Planning under uncertainty
  - Which options would be selected in all market scenarios?
  - What is the least cost way forward under different market conditions?
- The reliability of the system
  - Including under different RES penetration scenarios
- The optimization of imports/exports from/to neighboring countries to inform PPA contracts
- Total quantities of fossil fuels used
